

# Morphological Image Processing

Once segmentation is complete, morphological operations can be used to remove imperfections in the segmented image and provide information on the form and structure of the image

In this lecture we will consider

- What is morphology?
- Simple morphological operations
- Compound operations
- Morphological algorithms

# 1, 0, Black, White?

Throughout all of the following slides whether 0 and 1 refer to white or black is a little interchangeable

All of the discussion that follows assumes segmentation has already taken place and that images are made up of 0s for background pixels and 1s for object pixels

After this it doesn't matter if 0 is black, white, yellow, green.....

# What Is Morphology?

Morphological image processing (or *morphology*) describes a range of image processing techniques that deal with the shape (or morphology) of features in an image

Morphological operations are typically applied to remove imperfections introduced during segmentation, and so typically operate on bi-level images

# Quick Example

Image after segmentation

Image after segmentation and  
morphological processing

# Structuring Elements, Hits & Fits

Structuring Element

**Fit:** All *on pixels* in the structuring element cover *on pixels* in the image

**Hit:** Any *on pixel* in the structuring element covers an *on pixel* in the image

All morphological processing operations are based on these simple ideas

# Structuring Elements

Structuring elements can be any size and make any shape

However, for simplicity we will use rectangular structuring elements with their origin at the middle pixel

Structuring  
Element 2

# Fundamental Operations

Fundamentally morphological image processing is very like spatial filtering

The structuring element is moved across every pixel in the original image to give a pixel in a new processed image

The value of this new pixel depends on the operation performed

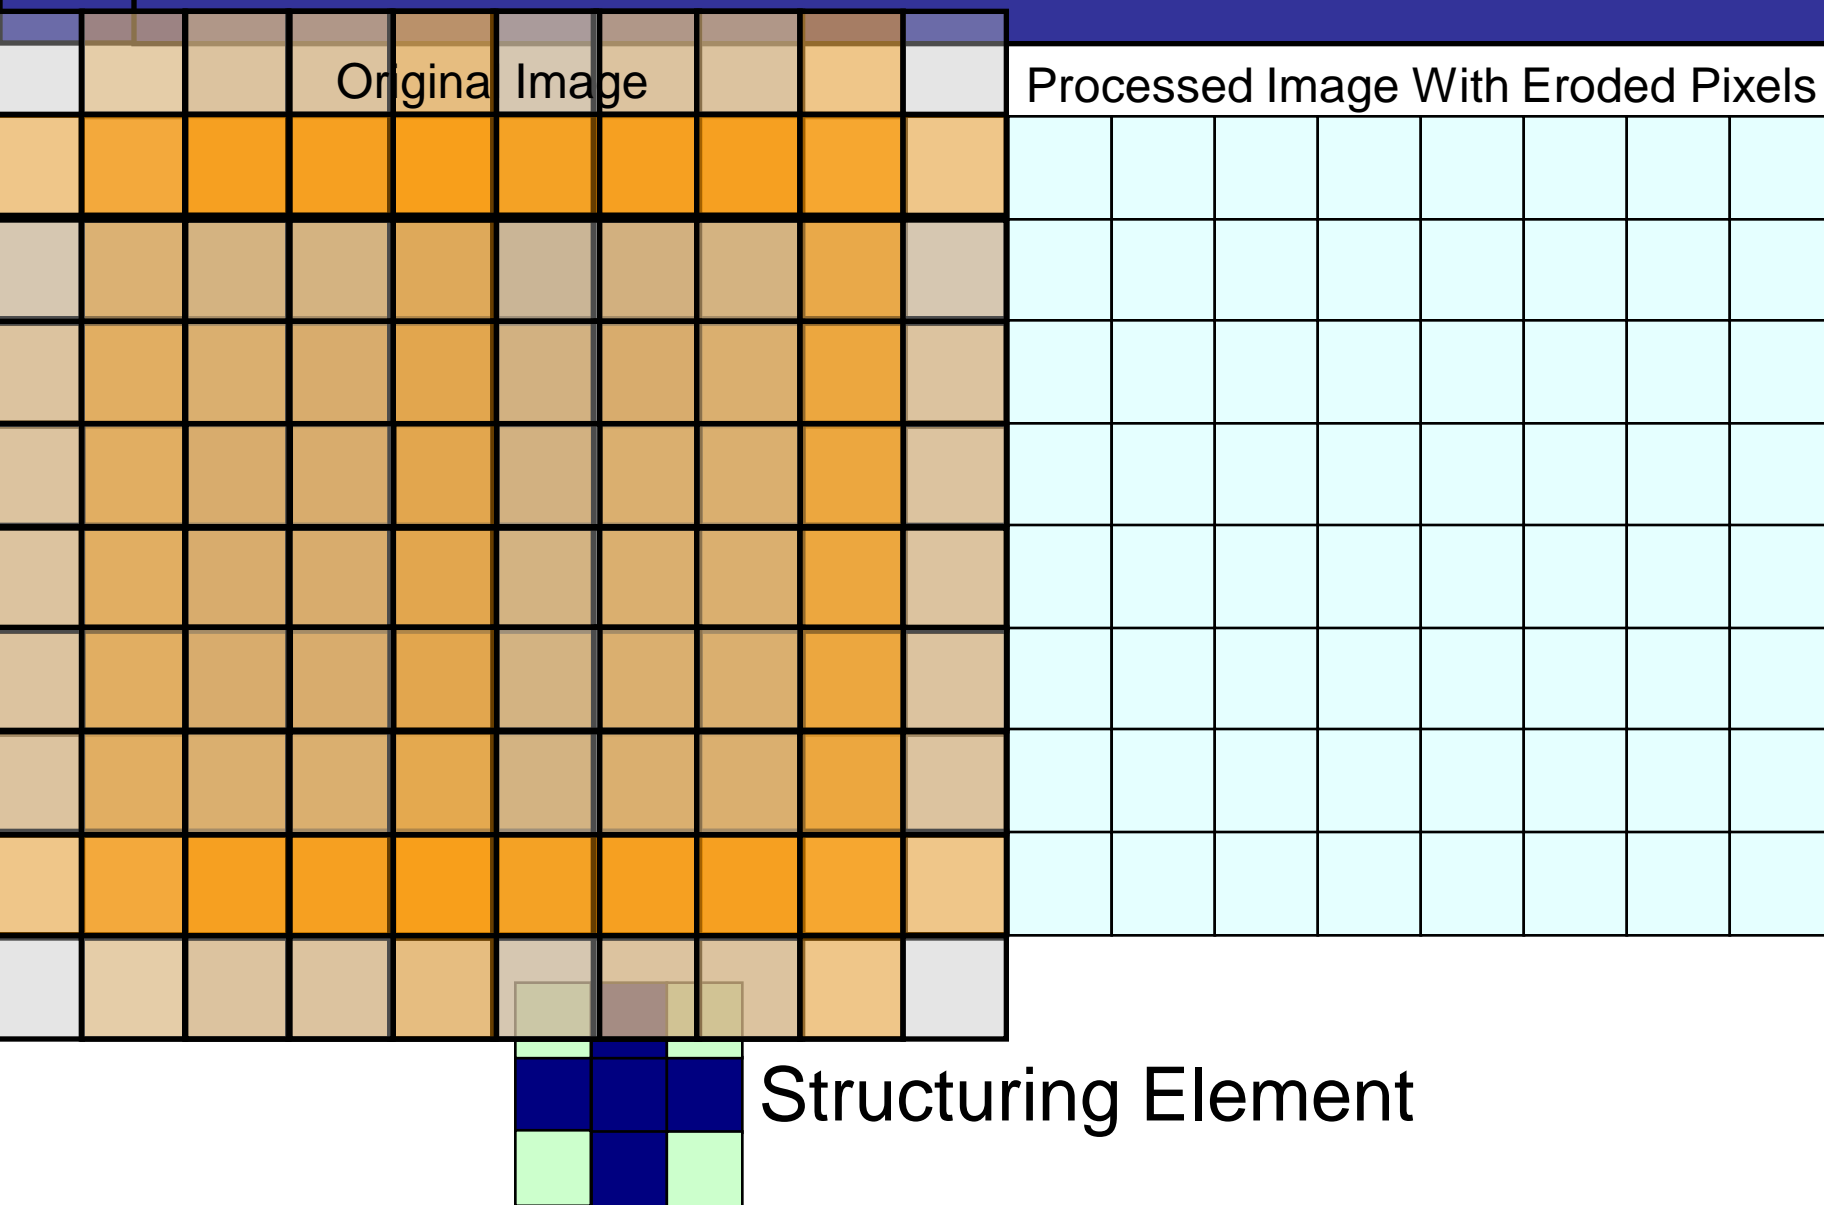

There are two basic morphological operations: **erosion** and **dilation**

Erosion of image  $f$  by structuring element  $s$  is given by  $f \ominus s$

The structuring element  $s$  is positioned with its origin at  $(x, y)$  and the new pixel value is determined using the rule:

$$g(x, y) = \begin{cases} 1 & \text{if } s \text{ fits } f \\ 0 & \text{otherwise} \end{cases}$$

radius 10

After erosion  
with a disc of  
radius 5

After erosion  
with a disc of  
radius 20

# What Is Erosion For?

Erosion can split apart joined objects

Erosion can strip away extrusions

**Watch out:** Erosion shrinks objects

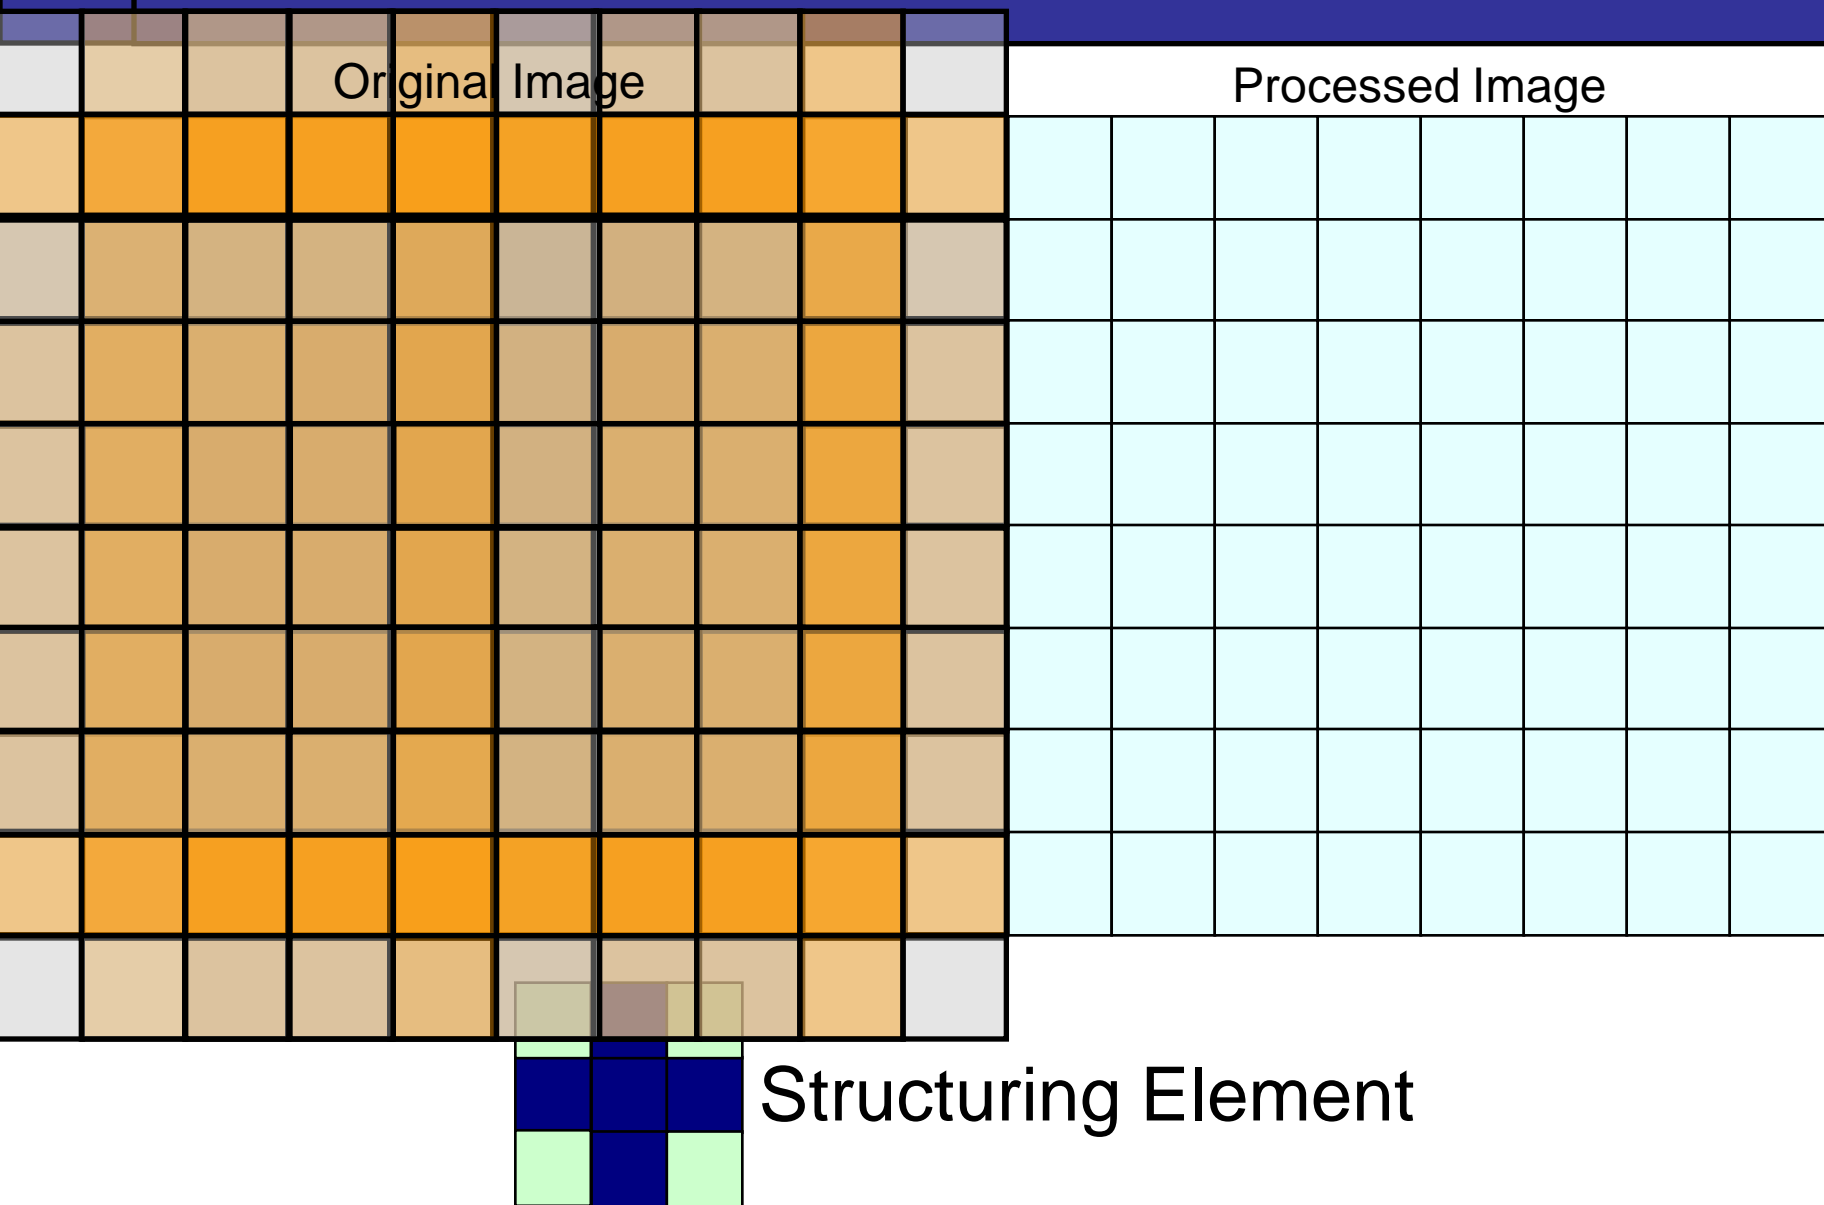

Dilation of image  $f$  by structuring element  $s$  is given by  $f \oplus s$

The structuring element  $s$  is positioned with its origin at  $(x, y)$  and the new pixel value is determined using the rule:

$$g(x, y) = \begin{cases} 1 & \text{if } s \text{ hits } f \\ 0 & \text{otherwise} \end{cases}$$

element

**Watch out:** In these examples a 1 refers to a black pixel!

# Dilation Example 2

Original image

Historically, certain computer programs were written using only two digits rather than four to define the applicable year. Accordingly, the company's software may recognize a date using "00" as 1900 rather than the year 2000.

After dilation

Historically, certain computer programs were written using only two digits rather than four to define the applicable year. Accordingly, the company's software may recognize a date using "00" as 1900 rather than the year 2000.

# What Is Dilation For?

Dilation can repair breaks

Dilation can repair intrusions

**Watch out:** Dilation enlarges objects

More interesting morphological operations can be performed by performing combinations of erosions and dilations

The most widely used of these *compound operations* are:

- Opening
- Closing

The opening of image  $f$  by structuring element  $s$ , denoted  $f \circ s$  is simply an erosion followed by a dilation

$$f \circ s = (f \ominus s) \oplus s$$

Original shape

After erosion

After dilation  
(opening)

Note a disc shaped structuring element is used

Structuring Element

The closing of image  $f$  by structuring element  $s$ , denoted  $f \bullet s$  is simply a dilation followed by an erosion

$$f \bullet s = (f \oplus s) \ominus s$$

 $A$ 

Original shape

 $A \oplus B$ 

After dilation

 $A \bullet B = (A \oplus B) \ominus B$ After erosion  
(closing)

Note a disc shaped structuring element is used

# Morphological Processing Example

Using the simple technique we have looked at so far we can begin to consider some more interesting morphological algorithms

We will look at:

- Boundary extraction
- Region filling

There are lots of others as well though:

- Extraction of connected components
- Thinning/thickening
- Skeletonisation

# Boundary Extraction

Extracting the boundary (or outline) of an object is often extremely useful

The boundary can be given simply as

$$\beta(A) = A - (A \ominus B)$$

# Boundary Extraction Example

A simple image and the result of performing boundary extraction using a square  $3 \times 3$  structuring element

Original Image

Extracted Boundary

Given a pixel inside a boundary, *region filling* attempts to fill that boundary with object pixels (1s)

Given a point inside here, can we fill the whole circle?

The key equation for region filling is

$$X_k = (X_{k-1} \oplus B) \cap A^c \quad k = 1, 2, 3, \dots$$

Where  $X_0$  is simply the starting point inside the boundary,  $B$  is a simple structuring element and  $A^c$  is the complement of  $A$

This equation is applied repeatedly until  $X_k$  is equal to  $X_{k-1}$

Finally the result is unioned with the original boundary

# Region Filling Step By Step

# Region Filling Example

Original Image

One Region  
Filled

All Regions  
Filled

The purpose of morphological processing is primarily to remove imperfections added during segmentation

The basic operations are *erosion* and *dilation*

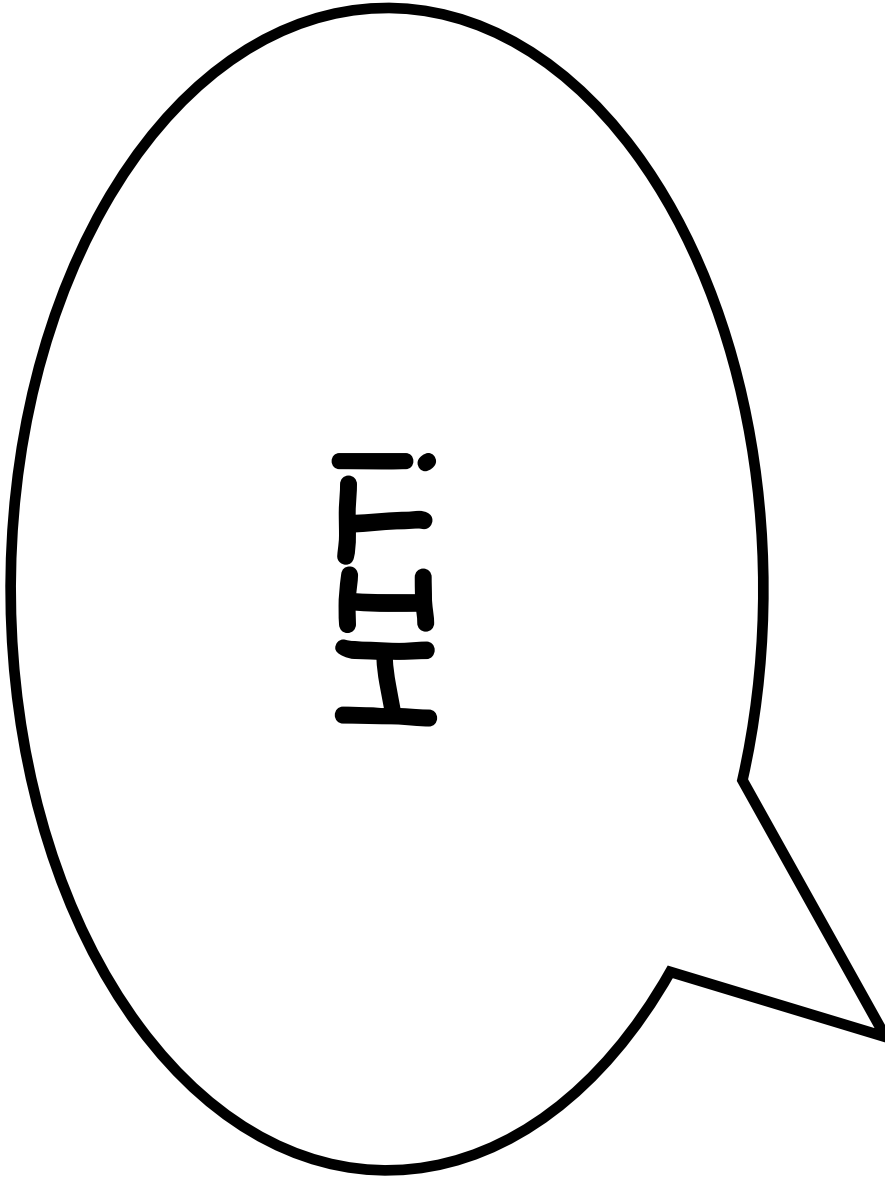

Using the basic operations we can perform *opening* and *closing*

More advanced morphological operation can then be implemented using combinations of all of these
